ABSTRACTTORONTO WOOD WASTE SURVEY

Fibrecon 80 was retained by the Ontario Ministry of Energy to investigate wood residue production and disposal in the area generally within 25 km of central Toronto. The objectives were: (1) to determine volumes, types, availability and security of supply of ungraded wood biomass residues being produced; (2) to determine the volumes and identify the use of wood biomass residues presently utilized; (3) to investigate current disposal methods; and (4) to investigate sustainable annual wood residue supply potential and delivered costs to potential central wood residue processing plant sites.

Data was collected on the supply of wood residues based on the following sources: manufacturing residues; shade tree improvement and removal residues; and building demolition residues. Accuracy of the data was ensured by personal interviews with residue producers, on-site inspection of residues produced, and a mini-survey of wood residue dumping at all major landfill sites.

Data was also collected on wood residue utilization and disposal based on the following sources: wood processing industries; municipal government departments responsible for shade tree and hydro line improvement and maintenance; private shade tree improvement contractors; waste disposal contractors; and building demolition contractors.

A master list of industry and municipal government groups that generate and/or dispose of wood residues was prepared.

A wood waste biomass analysis was conducted to quantify geographically the wood residues produced by types, moisture content, degree of contamination and current utilization/disposal methods.

Suitable wood residue processing plant site alternative locations were selected; sustainable annual wood residue supply potential at the sites was identified; and delivered costs analyzed.

000004

EXECUTIVE SUMMARY

This study was commissioned by the Ministry of Energy, Ontario, to investigate potential sources, types and volumes of ungraded wood residue materials and the extent to which they can displace significant volumes of fossil fuels.

The Study Area - generally within 25 km of central Toronto, extended to include fringe areas with good transportation corridors.

Study Participants totalling 1,092 are summarized as follows:

Municipal Shade Tree Improvement & Removal	=	32 (3%)
Private Shade Tree Improvement & Removal		
Contractors	=	64 (6%)
Waste Disposal Companies	=	103 (9%)
Manufacturing	=	893 (82%)
Total Population Surveyed		<u>1,092 (100%)</u>

Collectible Volumes - it is estimated that the manufacturing sector produces 164,000 bone dry tonnes of wood fibre residues annually within the study area, of which 146,000 b.d. tonnes is considered collectible.

Energy Equivalents - the 18,000 b.d. tonnes of wood residues currently utilized in-house for energy purposes in the study area represents fossil fuel savings equivalent to approximately 9.2 million litres of oil annually (58,000 barrels). The energy equivalent of the collectible volume of wood residues (146,000 b.d. tonnes) is approximately 75 million litres of oil (470,000 barrels).

Geographic Distribution - the availability of the collectible volumes of wood residues in the study area is as follows:

000005

Metropolitan Toronto	45%
Regional Municipality of Halton	4%
Regional Municipality of Durham	8%
Regional Municipality of York	26%
Regional Municipality of Peel	17%
	100%

Analysis of the study data pertaining to geographic location of wood fibre residues, types and volumes, moisture content and disposition, appear in sections 5 and 6 and are presented in detail in Exhibits 1 to 10.

The data summary sheets are included in Appendix 1.

The directory of residue producers in the manufacturing sector is submitted as an addendum to the Report.

In summary, the report indicates that substantial quantities of collectible wood residues are available for conversion either in-house or at a central plant. Greater use of this valuable resource as an alternative energy source is desirable to reduce consumption of fossil fuels, while at the same time reducing its disposition in landfill sites, thereby reducing costs for the producer.

INTRODUCTION

The Province of Ontario currently produces about one-quarter of its energy needs from resources in Ontario, mainly electricity from hydraulic and nuclear sources. The Ministry of Energy goal is to produce 37.5 per cent of Ontario's total energy supply from indigenous renewable resources by 1995.

MOE Energy Note, Appendix 7, states:

"Within that target, nearly four per cent of Ontario's total energy supply in 1995 is expected to be produced from waste and biomass. This includes wood and wood residue; agricultural resources and waste; municipal solid waste such as garbage and sewage sludge.

Wood and wood residue are expected to supply about half of the energy from waste and biomass -- or about two per cent of Ontario's total supply in 1995. That amount of energy would be equivalent to 15 million barrels of oil annually."

In pursuit of this objective, the Ministry of Energy commissioned this study to determine the opportunities for wood residues from secondary wood processing industries to substitute for fossil fuels in the Toronto region. The terms of reference for this study may be summarized as follows:

- determine volumes produced in oven dried metric tonnes (odt), types, availability and security of supply of ungraded wood biomass residues from primary and secondary wood processing industry, from municipal and privately operated shade tree improvement and tree removal programs, and from building demolition operations.
- determine volumes of wood biomass residues presently being utilized and for what purpose.
- investigate current disposal methods.

000007

- investigate the possibility that operators of waste disposal firms servicing the industry might individually or cooperatively assume the role of collection, processing and marketing of wood biomass residue for the production of usable energy.
- identify 2 or 3 suitable plant site alternatives in the region; identify average hauling distances and average delivered costs for each type of biomass; identify sustainable annual wood supply potential at these locations.

All quantities in the report are reported on annual basis.

1. MANUFACTURING SECTOR

The manufacturing sector is the largest contributor of usable wood residues, producing approximately 91% of the total residue volume produced. In order that wood residue volume data could be developed that would provide a high degree of accuracy for this sector, 497 plant visitations were made out of a total of 893 active wood-using companies. The remaining 396 wood-using plants were rejected at the outset because the type of operation, or size of the company indicated that residue volumes would be too small to be collectible.

This approach to the survey, therefore, resulted in virtually 100% coverage of the wood-using plants with potential to supply wood residues for recycling.

Of the 497 plants visited 231 were found to be producing collectible volumes of wood residues. Following is Manufacturing Sector Sampling Breakdown:

Total Population Surveyed	=	893 (100%)
Interviews - Collectible Volumes	=	231 (26%)
Interviews - Volumes not Collectible	=	266 (30%)
Rejected Participants (no collectible volume or badly contaminated residues)	=	396 (44%)

2. MINI-STUDY OF LANDFILL SITES

A mini-study of waste dumping procedures at four major landfill sites was carried out over a period of four days. The purposes of the investigation were

- a) to record weigh scale data directly related to the various types of wood residues to supplement available information to be used in developing volume-to-weight conversion factors;
- b) to determine the amount of non-wood waste materials in mixed loads dumped by waste disposal operators;
- c) to discuss with operators of the landfill sites the impact of seasonality on wood waste dumping brought on by increasing use of wood-fired energy systems (primarily residential at this time);
- d) to observe the dumping of wastes from building demolition operations prior to further investigation of this potential source of wood fibre residues.

The earlier discussions with senior waste management staff in the municipalities, and the on-site study at the landfill sites provided useful data for developing volume-to-weight conversion factors, and substantiated earlier conclusions with respect to the following factors pertaining to wood fibre waste disposal and recycling:

- a) wood fibre is one of the less desirable wastes at landfill sites because it is not easily compacted;
- b) loads of wood fibre waste delivered to landfill sites by waste producers frequently contain some non-usable waste, but in general, the amount of contamination is within manageable levels;

000010

- c) wood fibre residues delivered to landfill sites and/or transfer stations are frequently unusable because little incentive exists for disposal companies to modify current collection systems to keep wood fibre waste separate from other waste materials;
- d) building demolition waste no longer has potential for wood fibre recovery because of the substantial volume of lumber salvaged, which results in only highly contaminated residues delivered to landfill sites;
- e) the increased use of wood in residential heating has a major impact on the volume of solid wood waste dumped, and accounts for the considerable decrease in volume evident in the winter months.

3. SHADE TREE IMPROVEMENT & REMOVAL

A mini-survey of wood residues production to determine the energy recovery potential from residues developed in this sector included interviews with the following:

- 1) all Municipal Government Parks & Recreation Departments,
- 2) all Municipal Government Hydro Departments,
- 3) a total of 22 private shade tree service companies believed to be performing 80% of the total work of this nature.

It was found that in all instances, records of work performed and tonnages of residues developing were incomplete due, primarily, to the following:

- 1) tonnages of residue chips used in-house by the municipalities for mulchings and for park trails are unrecorded,
- 2) tonnages of residue chips given away to nurseries, etc., are unrecorded,
- 3) tonnages of solid wood given to homeowners for fuel (virtually 100% of total production) are unrecorded,
- 4) records of residues production by private contractors fulfilling municipal government contracts and operations in the private sector are incomplete.

The unreliable wood fibre residue production data available necessitated that estimates be developed based on recorded residues volumes where available, and supplemented with estimates developed from other available information. Exhibit 1, overleaf, although imprecise, is the consultant's best estimate of wood fibre residues developing in this sector:

000012

Exhibit 1

WOOD FIBRE RESIDUE PRODUCTION
FROM SHADE TREE IMPROVEMENT AND TREE REMOVAL PROGRAMS
in B.D. Tonnes/year

SOURCE	UTILIZATION/DISPOSAL			TOTAL
	Chips Used for Trails & Mulching by Municipalities or Given Away	Solid Wood* - Private & Munic. for Fuel	Landfill Chips, Brush & Solid Wood	
Municipal Government	2,500	900	3,700	7,100
Private Contractors	3,000	500	3,900	7,400
TOTAL	5,500	1,400	7,600	14,500

*Estimated volumes developing from shade tree pruning and removal of 5,000 shade trees annually, based on data supplied by municipalities and private contractors.

The potential from shade tree removal operations is already being realized. The total estimated 1,400 b.d. tonnes of solid wood residues developing each year in this operation is now being recovered by the public for use in residential wood-fired energy systems. Assuming the heating value of this material averages 8,500 btu per pound this represents fossil fuel savings equivalent to 716,000 litres of oil (4,500 barrels).

The high moisture content of the remaining wood waste from this source precludes its utilization as energy fuel at this time. However, if future demand warrants, these residues could be dried to produce an acceptable, efficient fuel for industrial type energy systems. For this reason the volumes generated from these sources have not been included in the total collectible volumes of residues determined by the study.

000013

4. CURRENT DISPOSAL METHODS

Wood fibre residues produced in the study area are picked up by approximately 35 of the more than 100 waste disposal companies operating in the area, as well as directly by farmers, and a small number of wood waste commodity brokers. Material is resold to farmers for livestock and other bedding uses, as well as to fireplace log manufacturers, etc.

It was noted in the 497 plant visitations that less than 10 disposal companies were picking up the bulk of the wood residues. The remainder of the disposal companies do not ordinarily pick up wood fibre residues on a regular basis or in sufficient volume to significantly influence the total collectible volume in the study area. It should be noted that some manufacturers transport their own wood fibre residues to transfer stations and to landfill sites.

Discussions were held with the Waste Management Institute and two other major disposal companies to explore the possibility of modifying collection systems to isolate usable wood fibre residues found at plant sites from unusable waste being deposited in the same transport or compactor truck. Also discussed was the possibility that the disposal companies might be receptive to delivering wood fibre residues to central processing plant sites rather than to transfer stations or landfill sites.

The disposal companies were found to be receptive to separate collections for wood fibre residues and to the idea of delivering to central processing sites. They indicated this would enable them to reduce their customers' disposal costs by eliminating the tipping charge (currently ranging from \$12 to \$15/tonne at landfill sites up to \$23.50/tonne at transfer stations). Additionally, equipment more suitable for wood waste pick-up could be used, thus eliminating problems encountered in compacting this type of waste.

The possibility of waste disposal companies operating central processing plants was discussed with the disposal firms and it was found that this is a venture upon which several of the major operators would look favourably.

000014

5. ANALYSIS OF WOOD BIOMASS RESIDUE AVAILABILITY

5.1 Manufacturing Residues

It was determined that a total of 163,902 b.d. tonnes of wood fibre residues are produced annually within the study area. Excluding the volume used in-house (17,986 b.d. tonnes) for energy the collectible volume is 145,916 b.d. tonnes, comprising the following:

- 1) 44,933 b.d. tonnes of wood residue solids and dust currently being dumped. Approximately 34,000 b.d. tonnes of this volume will require processing into suitable particle size for automated wood-fired systems.
- 2) 100,983 b.d. tonnes of wood residue solids and dust currently being sold or given away by the residue producers to wood fibre residue commodity dealers, to farmers and to the public.

There appears to be few firm commitments of the residue volumes currently being sold or given away and little indication that the residue producers have any other interest than to dispose of their wood waste at the least possible cost.

Where sales of residues take place the monetary return to the residue producer at plant site is usually in the \$0.00 to \$1.00/tonne range with occasional returns up to \$5.00/tonne, depending on the type and quality of the residues.

The normal flow of wood residues to fireplace log manufacturers (estimated 14,000 tonnes/yr) and the volume of solid wood residues given away to employees for fuel (estimated 5,300 b.d. tonnes) is not expected to be greatly affected by increased demand for wood residues in the marketplace.

It would be reasonable to expect, however, that in a competitive market a substantial portion of the remaining 81,600 b.d. tonnes would become available for energy recovery.

000015

5.2 Shade Tree Improvement & Removal Residues

It is estimated that 14,500 b.d. tonnes of wood residues develop annually from shade tree removal and improvement operations by the municipalities and by private contractors. Because of the high moisture content these residues are not at this time a preferred fuel for energy recovery.

It is expected that the utilization pattern in this sector will continue to be as follows:

- 1) the 5,500 b.d. tonnes of chips currently used by the municipalities for mulching and for parks nature trails or given away will continue to increase with increasing demand,
- 2) the 1,400 b.d. tonnes of solid wood residues from tree removal operations will continue to be picked up by private individuals for fuel,
- 3) some of the 7,600 b.d. tonnes of wood waste from this program currently being dumped will revert to other uses as more brush chippers are introduced. The remainder may continue to be dumped because it is of too low quality to be considered for other uses.

Details of the consultant's findings with respect to geographic location, type of residues, moisture content, and current disposition are analyzed in Exhibits 2 - 10, following.

6. CENTRAL PROCESSING

6.1 Plant Locations

The selection of the two proposed residue processing plant sites is based on the study findings with respect to concentrations of residue supply in relation to main transportation facilities.

It should be kept in mind, however, that the final location of any processing plants will be greatly influenced by the proximity of major markets and the location of the largest producers of available wood residue volumes.

6.2 Supply

The only assured supply of wood residues available for central processing is the volume currently being dumped. This comprises approximately 45,000 b.d. tonnes of solid wood residues and mixtures of solid wood and dust residues from manufacturing operations. This will be supplemented by an undetermined volume of residues that would become available in a competitive market from the residue volumes currently being sold or given away (determined as 100,000+ b.d. tonnes). Excluded from this additional supply potential would be the estimated 14,000 b.d. tonnes currently being utilized in the manufacture of fireplace logs and the estimated 5,300 b.d. tonnes of solid wood residues given away to employees and others for fuel.

It is expected that a substantial volume of wood residues will not require processing and will be delivered directly to the customer during the high season and to the processing plant for storage only in the off-season.

6.3 Supply Distances

The distance from the areas of greatest residue supply concentration is generally less than 25 km. However, supplies located at greater distances are collectible if, because of better highway access, the travel time is comparable to that for close-in supplies.

Some of the average hauling distances to each of the proposed central processing plant sites are estimated as follows:

<u>To Site 1 - West from:</u>	Brampton	10 km
	Mississauga	8 km
	Etobicoke	20 km
	Rexdale	20 km
	Bolton	40 km
	Acton-Georgetown	40 km

<u>To Site 2 - East from:</u>	Scarborough	23 km
	Concord	25 km
	Newmarket	30 km
	Downsview	40 km
	Oshawa-Whitby	43 km

6.4 Factors Affecting Delivered Cost of Residues to Central Processing Plants

The cost of wood fibre residues delivered to central processing plants is not currently a significant factor in determining the selling price of this commodity.

There are two costs involved in waste disposal -- the pick-up and delivery charge and the dumping cost. The pick-up and delivery charge varies according to the time required to pick up the waste container and deliver it to the landfill site or transfer station. Average turn-around time in the study area for this service is estimated at 1.8 hours at a cost of \$65 - 70 per hour. The dumping cost varies, depending on the weight of the residues in the container. At landfill sites the charge is \$12.00 to \$15.00 per tonne, and at transfer stations \$2.00 per 85 kilograms or \$23.53 per tonne.

The waste disposal companies foresee no immediate change in their operating pattern. They would, however, be receptive to dumping wood residues at central processing plants at no cost to the plant, providing this did not result in extra transportation cost. If this should occur, the processing plant would be responsible for the additional cost. The residue producer would be relieved of the dumping cost and would not be responsible for other than the normal transportation cost.

It is this consultant's opinion that the "no cost" situation would prevail only until such time as the selling price for wood residues increases. The residue producer would then expect some further disposal cost relief and eventually, some return for the commodity. This trend is already established where farmers or wood residue brokers are picking up shavings and sawdust at the production site at no charge or at a nominal price for the commodity (frequently less than \$1.00 per tonne).

6.5 Operating Costs & Product Pricing

There are a number of situations involved in the operation of a central processing plant which affect production costs and selling prices. The most important of these are the type and particle size of the wood residues and the season of the year.

- During the period of high demand any residues not requiring processing should be transported directly from the producer's plant to the customer at minimal cost.
- During the low demand period all residues will be delivered to the processing plant for processing and/or storage.

If the present operating mode of the waste disposal companies prevails, all wood residues currently disposed of by dumping will incur only processing and/or storage costs, while the costs incurred for wood residues purchased at the producer's plant will be the purchase price plus the transportation cost. It is unlikely that any significant processing costs will be incurred for purchased residues because the solid residues portion of the total volume would be only a small fraction of the available supply.

The consultant's findings are that the assured and estimated wood residue supplies available to the central processing plants, the production costs and selling prices should approximate the following:

1) Assured Supply - 44,933 b.d. tonnes of wood residues currently being disposed of by dumping

- transportation cost	-	Nil
- processing cost	-	\$10.00/b.d.tonne
Total Production Cost	-	\$10.00/b.d.tonne

2) Negotiated or Purchased Supply - estimated to be 24,800 b.d. tonnes comprising 100% of the laminate board residues and 50% of the hardwood dust residue currently being sold or given away

- transportation cost	-	\$20.00/b.d.tonne
- purchase price	-	\$ 5.00/b.d.tonne
- processing cost	-	Nil
Total Production Cost		\$25.00/b.d.tonne

The current selling price of wood fibre residue dust or hogged residues approximates \$25.00/b.d. tonne in the off-season and \$30.00/b.d. tonne in the heating season, f.o.b. the processing plant. At current market prices the average return, excluding any storage costs that might be incurred, is estimated to be \$9.66/b.d. tonne in the off-season and, in the heating season \$14.66/b.d. tonne for the total volume of 69,733 b.d. tonnes handled. The potential fossil fuel savings effected by operation of the two central processing plants is estimated to be equivalent to 35,700,000 litres of #2 oil (224,000 barrels).

APPENDIX 7

ENERGY FROM WOOD FOR NON-RESIDENTIAL USE: A STATUS REPORT

Wood is an ancient fuel with a new future in Ontario.

With today's energy costs, it is becoming more and more economical for many Ontario industries, businesses, farms and institutions to convert to wood.

Wood energy systems on the market can convert wood or residue from pulp and paper mills and sawmills -- such as sawdust, bark and wood chips -- to hot air, steam, electricity and "wood gas", a kind of gas that can replace natural gas in some uses.

Ontario has an abundant supply of wood and wood residue. Pulp and paper mills, sawmills and other wood processing industries produce millions of tonnes of wood residue each year.

Some residue is currently converted to energy, primarily at pulp and paper mills. In fact, residue from Ontario's pulp and paper mills supplies about 40 per cent of their energy needs. Nevertheless, over a million tonnes of mill residue are either dumped or burned each year. Also, logging operations leave millions of tonnes of branches, stumps and tree tops on the forest floor.

In Ontario, wood and mill and logging residues have the energy potential of more than 50 million barrels of oil annually (enough to heat the equivalent of 2.5-million homes).

Wood is an important energy source for Ontario. The Ministry of Energy has supported the development of many wood energy projects in the province. They are designed to encourage the development of wood use technology by demonstrating that wood energy systems are economical and practical for a variety of uses.

These projects are part of the Ontario government's commitment to reduce oil consumption and to increase the supply of energy produced in Ontario.

1995 -- A GOAL

The Province of Ontario currently produces about one-quarter of its energy needs from resources in Ontario, mainly electricity from hydraulic and nuclear sources. The Ministry of Energy's goal is to produce approximately 37.5 per cent of Ontario's total energy supply from indigenous, renewable resources by 1995.

Within that target, nearly four per cent of Ontario's total energy supply in 1995 is expected to be produced from waste and biomass. This includes wood and wood residue; agricultural resources and waste; and municipal solid waste such as garbage and sewage sludge.

Wood and wood residue are expected to supply about half of the energy from waste and biomass -- or about two per cent of Ontario's total supply in 1995. That amount of energy would be equivalent to 15 million barrels of oil annually.

The target represents a three-fold increase from the nearly five-million barrels of oil equivalent (BOE) estimated to be produced today from wood residue by the forest products industry and from wood use in about 800,000 Ontario homes.

The following sources could supply the wood and wood residue needed to reach the 1995 target:

- bush residue - 8.4 million BOE*.
 - consisting of millions of tonnes of branches, tops and unwanted trees left after logging operations.
- tree plantations - 5.9 million BOE.
 - selected species of trees, such as fast-growing hybrid poplars, can be ready for harvesting in as early as two years.
- unused residue - 0.9 million BOE.
 - from pulp and paper, sawmills and other wood industries.

* One million BOE (barrels of oil equivalent) is enough to heat nearly 50,000 homes for a year.

ONTARIO WOOD ENERGY PROJECTS

The following wood energy projects in Ontario have received some form of assistance from the Ontario government. More detailed information on the various energy-from-wood projects assisted by the provincial government is listed in TABLE I at the end of this Note.

BioShell, a subsidiary of Shell Canada, turns sawmill residue into small, compressed pellets of wood called Energex fuel pellets. Plants in Iroquois Falls and Hearst make 200,000 tonnes a year of these pellets. Nearly all the pellets are used industrially, primarily by Abitibi Paper for fuelling boilers.

Grenville Christian College, a private school in Brockville, recently installed a wood burning system that provides hot water and space heating. Heating costs are expected to be about \$25,000 for the 1982/83 winter, far less than the previous year's \$100,000 oil bill. The system burns sawdust, wood chips and bark from nearby mills.

At Kakabeka Timber Limited, a sawmill in Kakabeka Falls near Thunder Bay, sawdust and wood chips replaced propane as fuel for a dry kiln. The system saves the company about \$70,000 a year in fuel costs.

The Levesque Plywood Mill in Hearst is experimenting with a new wood gasifier developed by Omnifuels Limited. The gasifier is designed to convert 27,000 tonnes of wood residue into energy annually, providing a potential savings of thousands of dollars a year in natural gas costs.

Foothill Greenhouses Ltd. of the Holland Marsh recently installed a sawdust-burning system to heat a greenhouse complex that grows cucumbers. Installed in mid-1982, the system is expected to save up to \$40,000 a year in energy costs.

Wood-to-energy technology is also being demonstrated at a greenhouse in the Holland Marsh. Greenhouse owner Jim Vonk hopes to save about \$14,000 a year by using wood waste instead of oil to heat his flower greenhouse.

On a smaller scale, farmer David Smith of Port Ryerse, near Simcoe, designed a system that burns sawdust, corn cobs, peanut shells and other kinds of waste to fire a 60-horsepower, restored locomotive boiler. The boiler provides the heat needed to dry grain and heat a small greenhouse that grows tomatoes. Much of the system was made with used parts.

In another small-scale demonstration project, a refurbished, turn-of-the-century steam engine will be used to supply some of the heating and electrical needs at the Lafleur Gardens greenhouse in Timmins. The steam engine, which is expected to be installed this spring, will be fuelled by wood and wood residue.

In the public sector, wood energy systems are expected to be installed in 1983 at two locations in Thunder Bay -- Hillcrest High School and Lakehead University. Wood energy systems are also planned for Kemptville Agricultural College, Oshawa's Kingsway College and the Rideau Regional Center in Smiths Falls.

EDWARDSBURGH STUDY

According to a recent Ministry of Energy study, there is enough wood in eastern Ontario to fuel a wood energy industry.

The Edwardsburgh Study confirmed that eastern Ontario is capable of producing more than one million dry tonnes of wood and wood residue annually, at a cost of up to \$50 per dry tonne. The supply could come from wood industries, logging operations, public and private woodlands, and hybrid poplar plantations.

About 600,000 dry tonnes of wood and wood residue are available annually at a maximum cost of \$50 a dry tonne. Potential hybrid poplar plantations in the area could provide close to another 400,000 dry tonnes at approximately the same cost.

HYBRID POPLAR PLANTATIONS

Rapidly maturing varieties of hybrid poplar that can be harvested in cycles of two to 10 years have been developed. One hectare can produce more than 17 green tonnes of these trees annually.

The Ministry of Energy funds research to improve the energy content (heat value) of hybrid poplars through genetic breeding at the Ministry of Natural Resources' Ontario Tree Improvement and Forest Biomass Institute in Maple, Ontario.

Under a current Ministry of Natural Resources program with Domtar Ltd., 20 square kilometres of hybrid poplars will be established in the Cornwall area by 1985 as a source of wood fibre for its pulp operations. Although these trees are destined to be pulp wood, much of the techniques being developed will be applicable to "energy" tree plantations.

WOOD-TO-METHANOL

The Ontario Energy Corporation is currently studying the possibility of using a mixture of natural gas from Alberta with Ontario indigenous resources -- including wood, wood waste, lignite and peat -- to produce methanol. The wood-to-methanol part of this program is at the research stage.

ASSISTANCE AVAILABLE

Many kinds of assistance for energy from wood and wood residue projects in all phases of development are available from provincial and federal programs.

The Ministry of Energy will share the risk of "first-off" demonstration programs.

The province will share the consulting costs for the necessary technical and economic feasibility studies. As well, the province will share the capital costs of installing a system that uses new technology or a new application of a proven technology.

Recipients of financial assistance from the province share in a monitoring and information transfer program designed to evaluate the performance of the technology and to generate "spin-off" applications.

The Canada/Ontario Conservation and Renewable Energy Demonstration Program provides \$58-million between 1980 - 1985 to help develop and apply innovative energy-conserving and renewable energy technologies in Ontario.

Some federal tax incentives are also available under Class 34 of the Capital Cost Allowance provisions and the FIRE program provides assistance with a grant of 20 per cent of the capital costs for eligible equipment.

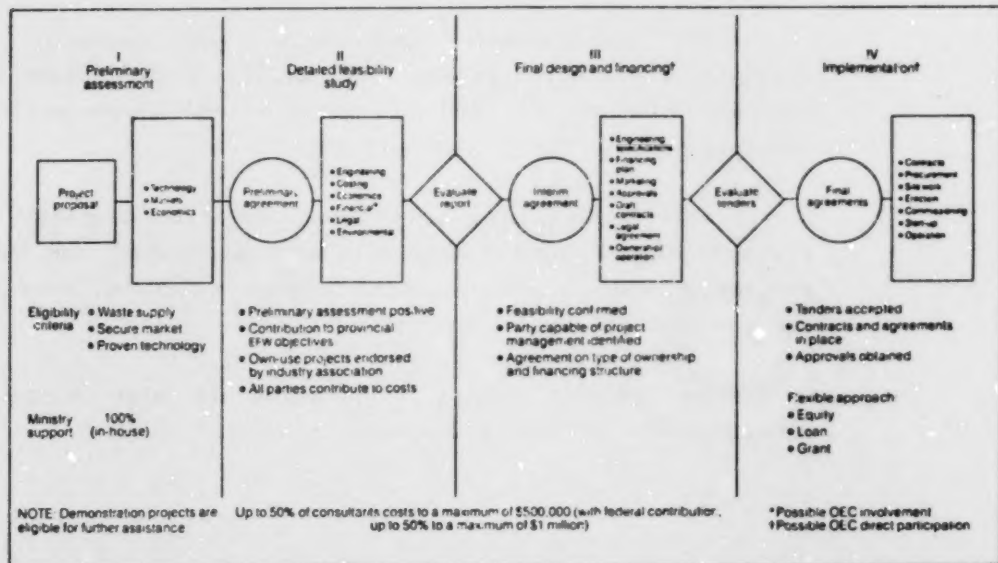

The Ontario Energy Corporation is also a potential equity partner in such projects.

CRITERIA FOR ENERGY FROM WOOD AND WOOD RESIDUE INVESTMENT

Before an investment in energy production can be considered, the following criteria must be met:

- a secure supply of inexpensive wood or wood residue must be available;
- a dependable market for the energy produced must exist;
- the conversion technology must be proven and have the potential for broad application in Ontario;
- economic and financial viability;
- a sound ownership, management and operation structure;
- and most of the capital costs of the project must be for Canadian-made products.

The following chart shows the kinds of assistance available from the provincial government for energy from wood and wood residue and other waste/biomass projects:

MORE INFORMATION

The immediate and longer-term opportunities for energy from waste and biomass between 1980 and 1995 are outlined in the Ministry of Energy publication: Energy from Waste: A Program for Ontario, published in March 1980.

Further information can be obtained from the Forest Resources Unit, Energy from Waste/Biomass Section, Ontario Ministry of Energy, 56 Wellesley Street West, 10th Floor, Toronto, M7A 2B7 Telephone: (416) 965-8059.
